PCT Patent Pending US2019/020863 European WO 2020/180307, China 2021

Be Different. Think Different. Do it with Taste. Make it a better Product

A bit of History

For me, it all began by purchasing my first Microbench kits in late 80's, and I couldn't take my hands off it. But optical kits have been around since 1920's made by Alfred Carlton Gilbert who is known as the father of Erector Set.

Microbench

An optimized construction of a binocular head (right) with Microbench system built by author using minimum number of parts. I have always felt Microbench didn't succeed as much as its Thorlabs' counterpart was because it lacked an easy to understand user's manual for its end users. Microbench's use of corner connectors made it capable of solving far more complex problems than its simplified Thorlabs counterpart.

In Optoform II concept, support rods act as corner connectors. We'll build a binocular head with Optoform II to compare its flexibility, and cost.

Optoform I

I invented, and filed a PCT patent for Optoform in 1993, hoping to offer a lower cost system than Microbench. Right, a motorized Biological binocular microscope built with original Optoform utilized concentric circular building blocks from 25 to 150 mm in diameter.

The capabilities of Optoform have been known by many research centers, and universities around the world. Complex optical cage systems are difficult to get started with, but those who do master it, can't live without it. Optoform I is still one of the most versatile erector sets offered to optial engineers, and optics lab technicians alike.

Optoform I introduced linear bearings: It consits of a stationary plate, and a translation pate pushed by micrometer.

It introduced up and down compatability between the mounts: Close up view of Littrow prism mounting screws (left) utilizing corner connectors. Opto-mechanics is all about details, and Optoform I handled every detail pretty well.

We have come a long way with Optoform II The new generation of optical Cage System

When visiting trade shows, and observing so many new products, I have often offended some sales people by telling them their product isn't genuine. An optical cage system should bring something new, and honest to its end users. If you think you could just take off one rod, or change anodization colors, people will say no to it. Although a one-rod or three rod cage system is not as good as a 4-rod arrangement that's an engineering decision, not an innovative one.

So after nearly 30 years past my original design of Optoform in 1993, I said Optoform II better be something phenomenal or I won't spend time on it. Luckily, the new idea I had about making them cheaper, and more versatile, led me to design a new form that could be produced out of extruded Aluminum - a drastic reduction in manufacturing cost.

Before signing off an M&A agreement with Edmund Optics to hand over Optoform I, we had been manufacturing it for 18 years. I know it takes a 5-axis CNC machine around 5 minutes to produce each mount. This drives the price to \$30 each. New Optoform II can be produced in about half that time, and half the cost.

Since Optoform II is less expensive, thinner, and lighter, you could divide your setups into sub-assemblies. Optoform II offers space frame components so you could build complete housings, and portable instruments. In upcoming pages, we'll review some real applications, and see how the new Optoform building blocks can be helpful in constructing them. These are culmination of many applications notes previously published in our quarterly magazine at optomechanix.org.

Ali Afshari CEO, Optomechanix

Main Design Advantages: Less expensive, more versatile, more compact, lighter weight, more rigid, accepts larger optics, allows assembly from modules, could use various size rods.

Standard Optoform mounts include 40-100, and 40-104. These 40x40 mm mounts can be mounted face to face, and side by side.

More advanced mounts can secure rods in diagonal direction, or be mounted in-line aginst support rods (right).

Everything you build is a module that can combine with other modules to build your setup.

Here's the first example: Various size halogen lamps can be centered by using proper length of rods to center the filament with the condenser optics (above). For short stroke focusing of optics, we'll be using the mounted lens cell itself for focusing. If the application requires a longer focusing range, we could also focus along the rods. There is a threaded bore pattern along the rods that allows multiplicity of interconnects between modules. Below is an alternate method to construct the same lamp housing.

When designing Optoform modules, some basic guidelines may be considered:

1) Anything less, then it wouldn't be functional

That's the philosophy I try to follow in module design. For those who have mathematical minds, a module is like an optimized equation. Once you simplify an equation to its minimal form, then you could save it, and use it anytime later.

2) Modules should allow chain connections / All screws accessable

It's usually a good idea to have male on one end, and female on the other as shown in short rod assemblies below.

Two cubes could be attached to the input/output of Swivel module (left) via M2.5 screws to build a spectroscope (right).

Building Modules From Discrete Parts

I will show you an example how to build an opto-mechanical assembly such as an autocollimator using a light source, an eyepiece, a focusable target, a beamsplitter, and an objective lens. Instead of starting with a central piece like the beamsplitter assembly, and adding components around it, we'll begin by constructing modules by picking different lengths of rods, and we'll combine them together later.

Lets build the halogen lamp first: Halogen lamps come in different filament heights, and could pick the appropriate rod length to center the filament, and then fine adjust it by sliding its socket within the mounting plates (below). The collimation optics consists of a concave mirror, and an Aspherical condenser lens. We could add 25 mm tubing to eachlens to focus them to the filament. Then there are more elements to add such as the target with perhaps a diffuser. The beamsplitter, and the eyepiece could then be added.

Adding them all together, the filament is focused on the objective lens surface. A flat mirror is usually placed in front of the objective lens, and the target is focused so that its image would fall on itself through the eyepiece. The beamsplitter angle, and the eyepiece is then adjusted to center, and focus onto the target.

Threaded bores on the sides, and counter-bores on the plates allow direct mounting of mounts at right angles.

Lamp

Mirror

Lamp

Socket

Condenser

Target

Housing

Thinner mounts means you could fit more components in a smaller package like in this beamsplitter assembly.

The mounts may be secured on side of rods to construct this illumination assembly for a Halogen lamp.

Here is an example of adjusting the position of elements within the mounts to build this target illumination optics.

Build the modules you need first, don't worry, you'll have plenty of ways to combine them together in your setup: You could attache mounts along the rods, across the rods, and in many other ways.

The fully assembled autocollimator on a post mount. Bore pattern on rods simplifies opto-mechanical interconnections. Instead of predictable assembly routines, Optoform II would stoke your imagination, and empower your creativity.

Opto-Mechanical Rigidity

Optoform has always been a "Whole Setting Concept" than being limited to only one size. Shown below, it could step up in size to build a complete sensor housing. All mounts offer direct upward / downward compatibility. All standard mounts (i.e., 40, and 74 mm square) are 6 mm thick, and utilize 6 mm rods. But how is this possible?

The clamping force in Optoform rods is by full size Allen cap screws. This provides far more rigidity than set screws utilized in prior art. The skeleton structures are further reinforced by pre-fabricated Aluminum covers (right).

The fact that these mounts are 40% thinner allows one to add interface plates (male/female) so the modules could come apart without losing their own identity as sub-assemblies. This also demands higher structural rigidity, and flatness between the mount, and the rods.

To make this work, sometimes it is necessary to logically follow through the final structure, and loosen, and tighten some of the rods to make sure there are full contacts between the joints. At the micronlevel, the structure itself would shift towards a solid / wobble-free, self holding support frame.

What would happen if you turn support rods to corner connectors? Unlimited mounting possibilites

Direct Right Angle mounting

Constructing a cube

Using Optoform 74 mounts: In real practice, you'll only do this once. Cubes are your basic elements to construct 3D structures. The height could range from 12 to 142 in 17 mm increments.

Securing mounting plates at right angles

Using counter-bores on the face of 74-100, and equally spaced M2.5 bores on the side of 74-100 or 74-104, two mounts may be joined together at right angles.

Using Optoform Accessories:

Utilizing 50-104 to secure 45° mirror mount 50-337 on mounting adapter 74-134. This centering disc is held at 3 points via M2.5 set screws (right).

Approach your final product

Optoform is the most innovative prototyping tool for product development. It is an iconic trait to create your new ideas, with design elegance, and value engineering. It provides both optical assembly, and housing, all self holding, and all self supporting. All Optoform components are made of Alluminum Alloy 60-61, anodized in dull black for durable low reflection finish.

A reversible concept

40-134

Optoform rods could be either bolted onto the mounts or the mounts could be secured onto the rods (using 40-134). The end result always grows with your imagination, and knowledge of the system.

Substantial cost savings: 1/3 price

Producing new Optoform mounts will take half the time it takes to produce the original mounts. This is because the bore location of new mounts is on their outer corners and this allows manufacturing through the extrusion process.

Lower cost is so central to justifying this new concept. If the mounts cost as much as before, end users would end up disassembling them to use the parts for their next project. So the whole modularity concept would fall apart.

At the same time, high precision / tight tolerance mounts are necessary in opto-mechanics that cannot be sacrificed to cut cost. We have balanced this by incurring some cost to maintain precision where it is needed. Each module built with Optoform must have parallel / flat ends after assembly, and this requires perpendicular cuts on extrusion bars, as well as precision hole pattern on rods.

To achieve this high precision, we will start with a competitive price of \$20 each for our standard mounting plates. As we set up high volume manufacturing, and the extrusion dies are tested, and receive customer feedback, we'll be able to gradually meet our projected lower manufacturing cost by 2023. Labs will be able to buy 10 mounts instead of 3 made by our closest competitor.

Optoform 40 Opto-mechanical Componets

40-100 Standard Mount 25

Basic building block for optical setups with 25 mm mounting bore to secure 25 mm mounted optics, and accessories. It has four 2.5 Ø mm counter-bores and four M2.5 tapped bores. May be mounted on support rods via M2.5 screws. Mounting plates may be secured together face to face, or at right angles via 40-104.

40-100S Standard Mount 30

Identical to 40-100 but with 30 mm clerance aperture.

40-102 Compact Mount 25

Compact mount intended to secure on two rods to support 25 mm mounted optics, and accessories. There are two M2.5 tapped bores at their base, 17 mm apart, that allows mounting to other mounts at right angles via M2.5 screws.

40-104 Right Angle Mount 25

Allows direct mating of two adjacent mounts at right angles via two M2.5 mounting screws. It takes two pairs of 40-104 and 40-100 to construct a cube. A better alternative would be to utilize four rods.

40-104S Right Angle Mount 30

Identical to 40-104 but with 30 mm clearance aperture, and no counterbore.

40-106 Mating Plate 25

Identical to 40-100 but with opposite counter-bores, and tapped bore placement to allow securing the two mounts together. By utilizing 40-100, and 40-106 on mating ends of subassemblies, they can be attached, or detached while maintaining their own function, such as a Halogen lamp assembly, or beamsplitter housing.

40-106S Mating Plate 30

Identical to 40-106 but with 30 mm clearance aperture.

40-108 Intermediate Mount 25

It creates optical paths in between two rods, without causing mismatch to an assembly. For example, by adding two 006-23 rods to 40-108, its length will match with rods 006-74. The formula to obtain correct rod lengths is:

L1 = (L2 - 28 mm) / 2 Where L1 = Shorter rod, L2 = Longer rod

40-110 Sliding Mount 25

Can be inserted in between two rods to shift the position of optical axis along the rods, i.e., where the position of eyepieces in a binocular application needs distance adjustment. It may also be utilized to interconnect two or three rods at right angles.

40-118 Standard Mount 25

Accepts 6 mm rods in diagonal direction and mates to 40-100, and 40-106 to build three dimensional structures. Accepts Micromax 25 tubes, and other mounted optics.

40-130 Microbench Adapter 25

Has matching bore pattern to mount against Microbench cube 25/30, and mount 06-1041, to have full integration with Microbench mounts, and accessories.

40-134 Side Mount 25

Accepts M2.5 screws from inside out to mount along the rods with M2.5 bore pattern. It will secure optics along the 6 mm rods.

40-136 Side Mount 25C

Identical to 40-134 but in the compact form of 40-102 to mount along the rods with M2.5 bore pattern.

Special Mounts 40

40-112 Compact Mount 40

Secures Optoform accessories on top of 74-134 to secure 25 mm mounted optics, and various Optoform accessories. Designed to secure optics inside 40 mm tall instrument base (above).

40-120 Combination Mount 25

It is two 40-104 mounts placed side by side, sharing the two middle rods. Supports two parallel optical beam paths, 34 mm apart. For binocular vision systems, and Z-path beam folding to shorten the size of an optical layout.

40-124 Side Mount 30, 40/74

For side mounting Optoform 40 mounts to mounts 74. Has four mounting bores to accept mounts 40 at its center. Mates with 40-126. Secures 30 mm mounted optics via M2.5 set screws.

40-126 Side Mount 30, 40/74

Identical to 40-124 but with mating bores to be secured face to face with 40-124. Allows end to end connection of modules, and mates directly with 74-100 mounts. Secures 30 mm mountd optics via M2.5 set screws.

40-128 Inclined Tilt Platform 25

For constructing a binocular head with 60 degree inclined viewing. Mates with Optoform 40 mounts in both axial and orthogonal directions via support rods. A specially designed rod for constructing the binocular head is avaiable 006-128 with L = 128 mm. This rod has the correct length to work with 40-108. Secures 25 mm mountd optics via M2.5 set screws.

Optoform 74 mounts

74-114 Side Mount 74

Identical to 74-100, and 74-104, but with portions removed to allow securing it to rods internally rather than externally via M2.5 screws. This mount could be secured anywhere along 2, 3, 4 rods.

74-100 Standard Mount 74

Mounting plate 74-100, and 74-104 have matching 2.5 mm counter-bores, and tapped bores, 51 mm apart, to allow securing them face to face, i.e., for joining two sub-assemblies.

The 17 mm spaced mounting bores on its side will mate directly with Optoform 40 mounts. The 34 mm spaced mounting bores are to interface to other 74 mouns, or side mounts 40-124, and 40-126.

Will secure 60 mm mounted optics, and centering discs. Accepts Optoform 40 mounts on its M2.5 side bores.

74-104 Mating plate 74

Identical to 74-100 but with 51 mm spaced threaded bore pattern to mate face to face. This orients the rods on the top, and bottom of the mounts for easy assembly. For side bore pattern, please refer to 74-114 description.

74-134 Mounting Adapter 60

Accepts Optoform 40 mounts, Microptic 50 (38 mm BC), or 2x2 mounts (48 mm BC) to integrate full range of classic Optoform accessories. It is secured in place via four M2.5 screws, 90 degrees apart, and is not intended for centering. The hole pattern is complex but it's much easier during use.

Instrument base constructed with 74-120, 40-124, and 006-40 rods (right). The sides of this assembly may be covered by our Aluminum sheets with hole patterns that match the side bore patterns on the mounts. Aluminum sheets provide structural rigidite, light seal, and dust protection for the inner optics.

74-106M Focusing Module

Focusing module consists of three mounting plates 74-106, -108, and -110. Two linear bearings guide the stage, while a motorized or manual micrometer positions the stage along its 80 mm precision ground guide rails. The focusing stage is put together with four Aluminum rods, and structurally reinforced by thin sheet covering.

X-Y stage 74-200 may be secured on its translating plate (74-108) to consruct a X-Y-Z stage for microscopy applications.

74-120 Combination Mount 74x142

Combines two optical 74 mounts, 68 mm apart. Accepts Optoform 40, and 74 mounts on its sides, i.e. 40-124 to create instrument platforms (below).

74-200 X-Y Stage with sample

holder 120-420, 13 mm Travel

This low profile X-Y stage is designed to secure samples for microsocpy applications. It works with focusing stage above to create a manual or motorized X-Y-Z satage. Accepts 50 mm diffused glass, 1 mm thick.

40-148 Dichroic Filter Slider

Accepts standard 25.5x38 mm beamsplitters for Zeiss Axiovert microscopes. Filter slots have a lip to prevent filters from falling off, and two M2.5 set screws, and spring washers to secure each filter in place.

This mount provides 24 mm clearance aperture at 45 degree sliding position guided by twelve 6 mm rods arranged together with end connecting adapter 00- (below).

40-150 Filter Holder Slider

Accepts standard 25 mm Ø mounted filters, for Zeiss Axiovert microscopes. Filter slots have a lip to prevent filters from falling off, and M2.5 set screws to secure each filter in place. 24 mm clerance aperture.

40-146 Spacer Plate 25

Provides clearance space for slider filter assembly. May also be utilized to shield off-axis light coming through, from the edges of open mounts like 40-102, or 40-134.

00-248	Ball driver set 1.27, 1.5, 2 mm	For constructing Optoform 40, and 74 assemblies
006-40F	6 mm rod, L = 40 mm, set of 12	Special 6 mm rods with M2.5 threaded ends, with detent

Cover Plates

Sheet covering in Optoform may be easily cut to size by household shears. There are also nibling tools available to provide clearance notches for mounting screws.

Cover plates are cut at the center-line of M2.5 screw bore pattern around their periphery. This allows cover plates to lay side by side around the space constructed by mounting plates, and support rods. In optoelectronics projects, cover plates may be drilled, and nibbled to secure electronics connectors, and switches. The standard color for cover plates is anodized light gray. Unanodized version of cover plates are also available to take any desired color.

From basics all the way to highly advanced setups: Building a Telescope

You'll be able to construct these examples such as this simple telescope with parts from the basic **Basic Optoform kit 40-706**. This kit contains some Micromax parts such as an eyepiece holder (25-354), and an objective holder (25-198). The objective holder secures 25 mm mounted lenses such as f = 150mm (20-022) from the **Basic Optics Kit 20-914**. All our 25 mm lens cells can screw directly to Micromax tubing (25-128 or -130) but the 150 mm plano convex lens faces the wrong direction. This is how the lens cell adapter 25-198 becomes useful. Other tubes could also mate together via retaining rings 25-306, such as eyepiece holder 25-354, and tube 25-128 as shown below.

We'll use two mounting plates 40-100, and 40-106 to secure the eyepiece at one end, while securing the objective at the other. Optoform 40 assemblies are built like stackable cages, to allow their reconfiguration in the most modular way. The focusing is performed within the mounts via Micromax tubing.

Telescope with right angle viewing

The advantage of Optoform's modularity can now be examined when building this simple telescope with right angle viewing. Basically, we'll take out the eyepiece of the first telescope we built, and build a cube around it and a mirror holder to bend the light 90 degrees.

Optoform 40 is so compact that we need to extend it on one end to secure the existing mirror holder 50-352, and be able to center the mirror on the main optical axis.

There are several ways to accomplish this. We'll try the quickest method (Shown below), and that is to stack two mounts together: 40-100S, and 40-106. The 40-100S provides the tilt clearance for mirror mount 50-352 while the stationary end is behing held by 40-106.

The back end of tiltable mirror mount 50-352 is held by 40-100 while its front end is given space for its tilt adjustment inside the 30 mm clearance aperture of 40-100S.

Building a Halogen Lamp Housing

Before building microscopes, we'd better start with a lamp housing. Halogen is the most widely used light source other than LEDs.

The collimating optics 20-250, and concave mirror 20-480 are oriented in their lens cells such that Micromax extension tubes may be added to position them closer to the lamp (below). The Halogen beam is collimated, then focused to the sample by an additional lens (An optional double convex lens 20-108, f = 16 mm is recommended).

Building a Biological Microscope

Now that we have a proper ligh source, lets construct the microscope body. For standard microscope objectives, we need a 160 mm long tube. This is constructed by adding Micromax tubes 25-128, 25-130, and the eyepiece holder 25-354. The four tubes are joined together by three extended retaining rings 25-306. The objective mounting ring is assembled by adding 50-331, and 25-332 to the bottom of the tube. Sample holder spring plate 00-852 secures standard microscope slides.

More views of the same assembly

Building a Tilt Platform

Designing a platform for optical instruments in the lab has been long forgotten because so far, there has been noting available for it. This would be like owning a camera without a tripod! Instruments need platforms, and Optoform wishes to offer it to optical labs. Platform offers user interface, and ergonomics that you can't achieve by using post mounts that can only shoot up vertically from optical tables like a rocket.

20-823

under computer control.

40-106

25-354

Final Assembly

B

This is a classical instrument built with modern components. The first improvement that was offered to microscopes were a tiltable platform so the user could sit with his/her knees under a desk, and stare through the microscope eyepiece without neck strain.

The Autocollimator

Although already discussed in the introduction, more details of this design will be illustrated in its Solidworks modeling. Proper illumination solution for this instrument is to project the lamp filament on the objective lens. It ensures corner to corner illumination for the reticule while it is viewed through the eyepiece. There are two devices that would need to center its filament with the optical axis, and the other is 50-352 which uses a combination stack of 40-100, and 40-106S to position the beamsplitter 20-450 along the optical path.

Reconfigure

Now that we have built all the subassemblies, we could arrange them in many ways to construct the autocollimator. For example, the viewing eyepiece could be positioned horizontally, or at 90 degrees. The lamp cable could be oriented to extend from the back or to be attached from the side. All these re-arrangements can be accomplished by removing 6 connecting screws.

In optical instruments, the best way to connect power is to do it vertically (as shown

Building a Spectroscope

To build a spectroscope, we first need to construct a Swivel mount. The trick in here would be to utilize a pair of support rods 00-56, mounted to a pair of 40-106 mounts as shown below. Then a pair of 40-102 is mounted on both sides of mount 40-100. By inserting two cylinderical platforms 50-341 or 50-333, and two spacers 00-128, a swivel mount can be constructed as shown below. This assembly may be supported by inch or metric post mount.

Bulding a Sample Holder

This is the most undermined task in most labs. Building a sample holder involves a test tube being held on a reliable platform, and illuminated from the back by a relatively constant light source with a reasonably flat spectrum output curve. We could utilize the Halogen lamp we built for previous experiments to get us going on this. Test tube holder can be constructed with two mounting plates 40-102/136, and two rods; One could mount on the edge of the rod, and the other on the middle (R).

The most difficult task is to get the light source, and the test tube line up with spectroscope's input slit. In conclusion, this setup shows the possibility of performing tilts and rotation with standard optoform mounts. It may be applied to many other applications such as a tiltable viewing head for microsocpy.

Final Assembly

The main objective is to get the light source, and the test tube line up with spectroscope's input slit. The simplest way is to utilize a sliding mount 40-110, to allow up, and down adjustment of the test tube platform.

The result is a reliable test tube holder, and light source to line up with the slit input of the spectroscope. A thin plastic layer between 40-110, and the rods, provides variable height adjustment with adjustable friction.

On the next section, we are going to get into more sophisticated instrumentation with Optoform. These were child play just to get familiar with the basics.

eyepiece for image capture, and analysis.

Designing, and Building a Binocular Microscope

Building complex opto-mechanical instruments requires preassembled sub-modules, otherwise you'll be spending days designing it with solidworks or catia. Optoform speeds up the process with direct upward/downward compatible modules. If you decide to assemble them in a computer, you'd be putting together predesigned sub-assemblies.

You can order this viewfinder, as it will be an available module for the system. To adjust for the eye distance in a binocular head, sliding mounts 40-110 are designed to perform this task. The optical path inside the viewfinder is first bent 30 degrees via a Littrow prism for inclined viewing, and is split into two paths via a beamsplitter (Fig. 1). Three additional right angle prisms produce the proper separation between the two beams for binocular viewing. A pair of specially designed

40-120, and 40-126 mounts will be utilized to construct this assembly in its bent form. Sliding mounts 40-110 ride on two 128 mm support rods, that construct this compact 128 x 40 x 114 mm assembly.

While designing this somewhat complex arrangement, two new mounts, and a 128 mm long rod must be added. This is not a problem. Each module may contain specially designed mounts to perform a specific function. Mounts 40-126 are designed to be reversible, hence reducing the number of necessary parts. Refer to page 16 for detailed description of these mounts. Figure 1 shows a quick assembly trial to help us conceive its mechanical form.

To create mount 40-126, we'll be folding half of mount 40-120 (Fig. 2) around one of its mid rods. 40-126 is designed specifically to construct the 30 deg. inclined viewing (Fig.3). These basic building blocks will be utilized later to construct the rest of the microscope assembly. The viewing head is now ready to be built.

Fig. 1 Preliminary idea of a Binocular Head

If you are an optics fan, you'd appreciate what we are about to do. We have all used binoculars before but have you ever built one yourself? What it takes is a system capable of constructing it. While we were children, we used the Erector set to make anything we wanted but as we grew up, we were told everything was too complicated. To build a binocular, you'll need to go to Zeiss or Leitz factory, and they'll tell to sit behind an assembly line, or work with machinists to build its already designed parts. With Optoform, you don't have to. If you are able to create form, we'll make it functional. That's really our goal.

35

Mounting Prisms

What you experience in this assembly is more playful, and more fulfilling than being an assembler who works at Zeiss or Leica microscope factories. They aren't allowed to play, but you can!

Why not use an off the shelf viewfinder? You sure can, but these compact viewfinders have been replaced with large housings that cost too much. You may also have your own idea of adding a CCD camera inside it, or change the design to something that is more suitable for an upright microscope (light coming from above). In either case, Optoform gives you the freedom to implement it.

0

0

0

Sheet Covering

The idea is to be able to cut off extraneous light, and to prevent dust from entering the optics. For the moving parts sometimes you get lucky. The two eyepiece holders held by sliding mounts 40-110, can slide beneath a single cover sheet (34x34, below) like an off the shelf viewfinder. You could also see the edges in Optoform 40 assemblies are round. For a list of sheet covering sizes please refer to page 21.

The top, and bottom sheet covers are custom made. We'd offer you the entire unit, and you could either use it as what it is designed for, or disassemble it to make modifications. The prisms are held in place with three set screws which could also be utilized for alignment. There are thin brass sheets to protect the glass, also a thin cardboard packing as cushion.

Designing the focusing Module

The focusing module is a tricky one. Under high magnification, it should perform precisely without image drift, while under low magnification, it should have a wide travel range to accommodate objectives that are not necessarily parafocal. We will design an elaborate XYZ stage for the sample but for now, let's design a simple, motorizable system (switchable between manual, and motorized micrometers) utilizing classical Optoform's linear bearing concept (see page 4).

In its classical design, two linear bearings support the sample platform while a combination of a lift micrometer, and a return spring would precisely position the stage. The design is kept symmetrical to provide backlash free Z axis positioning. Four rods, and cover sheets support this 80x95x74 mm module. Because these modules are stackable, and the rods are side mounted, all the mating plates need to be paralleled (identical height on all four corners). With linear bearings, the mounts are already parallel, but for most assemblies it's best to adjust for parallelism. I'll show you how it's done.

Compact XY stage 100-300LP may be motorized by replacing its micrometers.

The XYZ stage assembly will have sheet covering to protect its inner components. The design of new Optoform modules allows chain connections. You'll see how this piece will fit to the rest of the system without any obstruction. The standard configuration is supplied with 13 mm micrometers which may be replaced with motorized micrometers as shown. 80 mm rods 006-80 support the assembly (see page 20 for rod lengths).

Expanding Optoform to Larger Mounts

As you see for constructing the rest of the microscope, we'll need larger mounts. In classic Optoform, we increased size and thickness of mounts, and support rods as the scale got bigger, but in new Optoform, we'll keep them the same! This is unheard of in Optomechanics. The advantage we have is full compatibility between every individual part in the system. What is allowing us to do this in module design is we could utilize sheet covering, and anything else that is necessary to achieve mechanical rigidity. Also in larger mounts, we could utilize larger rods within any of the modules, which could have any shape necessary. This would be impossible to accomplish with prior art.

The next size up is mount 74. This mount is a combination of 4 pieces of mount 40-100 (Fig.4). Combination mounts will always share rods between them. You'll see how this idea will allow construction of assemblies with extreme complexity. Again, the end user would just combine modules, while we'll handle the complexity ourselves. Our goal is to offer you a

construction system that you could also use to house your electronics. Optomechanics comes already included. Say you want to house a power supply: The stand-off for the electronics board, and the box could be built with Optoform. Every rod is 6 mm in diameter, and every mount is 6 mm thick, ready to be assembled. Your control panel would be one of the sides of the housing, while the box could have any width and height. Optoform mounts, and rods, and cover sheets could be on your electronics parts bin next to your soldering iron. You got the idea.

Parallelism

So far, the mechanical geometry of optoform has been 40x40, and now we are adding the next larger size: 74x74 mm. The combination mount for 74x74 would naturally be 74x142 mm. Our next size up would be 142x142 mm. How would you make all these sides parallel, and not come up with another eiffel tower?!

You could use a digital caliper to measure each side. Rod lengths are made with 0.01 mm accuracy but you could always press the assembly against a flat surface before tightening the screws, and you'll have good parallelism.

You could also use a height gauge or dial indicator as shown below. All four corners could have within 0.02 mm error. The Aluminum cover sheets would give structural rigidity to the assemblies. Before covering the space frame with sheet covering, the plates could be pressed against a flat surface on every corner before tightening rod securing screws.

Fig.4 Geometry of Combination Mount 74

Integrating the Modules

The current configuration allows implementation of both incident, and transmission illumination. The spacing between mounts 74-120 is 28 mm, and a new mount 40-112 is added to fit in between these mounts for securing all the necessary beamsplitters, and optical elements that are utilized in designing a Kohler illumination or an Epi-Luminiscent scheme. Any illumination optics we come up with is a stand alone module that may be taken off from the microscope to be replaced by an alternate design.

The base platform is currently designed in a T-shaped space frame that could hold some electronics. As the mounts get larger, their size to thickness ratio increases, and in larger mounts, they are not any thicker than elctronics enclosures with good heat dissipation. I will have to give you a few examples till you see what I mean by this. But for now, take my word for it: The new Optoform assemblies are perfect for wire routing, and electronic parts integration into the optics housing. I guess the easiest example would be housing a large CCD camera, mounted on 40-100 plate on top of the microscope. We'll construct one later. But what's missing in this microscope is the illumination optics. I'll explain that next. We have designed a special mount 40-128 for this purpose. It is mounted at several places around the microscope to show various light source mounting possibilities.

Adding Sheet Covering

The final assembly is to cover the instrument with sheet metal shell. With new Optoform this is easy because there are plenty of inexpensive pre-cut anolized Aluminum covers you could get to cover your design. Note where there are vertical rods, there are vertical curves around the body, and horizontal rods would result in horizontal curves on the housing contour. If you have conflict between two cover sheets, just cut the excess off with scissors. They do much better cuts on thin Aluminum sheets than heavy duty cutters. In any case, you'd also notice the condenser housing below the sample (60-430) is built with Micromax 60. This is an exact match to the inside clearance aperture of mount 74's.

Micromax 60 accommodates much bigger lenses. It is perfect for constructing condenser optics for illumination purposes. The Littrow prism can be replaced with a specially cemented version (right) to convert the binocular head to a trinocular observation head as show in this example.

Back Illumination

The microscope base in most microscopes are occupied by power supply electronics. This worked well for older generation microscopes because the weight of the power supply with its wire wound transformer would give the microscope a good balance. Today's switching power supplies are so light; they could be housed anywhere.

We haven't reached the electronics part yet, so it's pure optics for now. Most of the components like the lamp housing, mirrors, and tilt stages are borrowed from our classic Optoform parts catalog. Several views of the illumination optics housed inside the microscope's base is shown here. The upper platform securing the trinocular head, and objective turret is built with shorter rods (20 mm) to provide structural rigidity.

The illumination system

We suggested this illumination system last time as an optional configuration to convert the biological microscope to an epiluminescent or metallurgical system. We could now utilize it for inverted the microscope. The core of the illumination system is the Halogen lamp, and as a module, there are several ways to build it below. The condenser optics for inverted microscopy (right) has a large diameter to match the numerical aperture of the objectives. This is not so obvious in upright microscopes because it is hidden beneath the stage.

this 12V, 50W Halogen lamp.

Adding Modules Together

Adding the modules together is trivial in Optoform. The mounting plates that are utilized in making the modules are male/female oriented so every module could be secured to the next, thus erecting the assembly from ground up.

This is where the modularity concept of new Optoform is so useful. The user becomes system designer instead of dealing with bolts and screws. Ball tip hex drivers allow oblique access to connecting screws without obstruction.

Raiser Columns

Raiser platforms elevate each module to correct level so it would work with the rest of the system. In this case, the nosepiece turret is stationary, so it is up to the sample platform to be adjustable. So the focusing module not only acts as a raiser column (80 mm height), it also provides the focusing function in between.

Note that the major contributor to mechanical rigidity of raiser columns do not come from 6 mm support rods. For vertical forces, support rods do play a role, but in case of twisting/bending rigidity, reinforcement comes from cover plates. There is also the parallelism that has to be considered while stacking so many raiser columns on top of each other. If necessary, thicker rods may also be employed inside raiser columns.

Finishing up the optics Layout

The optical layout of the inverted microscope is pretty much done at this point, and what remains is the illumination system. The binocular observation provides 60 degree inclined viewing, with reasonable height to provide good ergonomics. If higher viewing level is required, raiser platforms, are available in both Optoform 40, and 74 to accomplish it.

An inverted microscope lets you pay more attention to your objective lenses, and the illumination optics because they are more visible, and easier to see. The tilted nosepiece turret is facing toward the operator (to prevent its collision with focusing module on the back wall). A cube 40 is utilized to extend the position n of binocular head, allowing the nosepiece turret to rotate without obstruction.

Note how the modularity scheme of Optoform has liberated it from the "through the rods" optical path to "outside of the rods" optical path. The nosepiece turret has always been a dilemma for the cage system construction but as you see in this assembly, it's out of the cage, enjoying fresh air.

Cube 40

00

Fold Mirror

Final Assembly

well, here is the entire system we built, and it measures only 200 mm in height. I just received an email from an optics student, asking me if I had a DIY guide to make this sytem so everybody could use. My answer was unfortunately no. The reality is only grownups could afford these optical kits, and its mechanical components to experiment with. Optical toys for children did have reasonable quality back in the 30's but with the introduction of plastics, children toys, telescopes, and microscopes have become so cheap that they don't play a great role model for optical engineering. Owning this system was my own dream when I was a child. The price difference is approximately 100 to 1 (\$75 to \$7,500).

The reason Optoform works so well is because of so many man hours in designing, manufacturing, and putting together its inventory of parts. The end user grabs a lens from a lens kit, and inserts it into the mount, and it's ready to go. You have to be a manufacturer to realize how tight the tolerances are for each, and every piece, and how many parameters, and mounting possibilities are considered before a new piece is added to the system.

By using, and evaluating this microsocpe, we can prepare it for the next step of construction: To finish it up with pre-cut sheet metal covers for added rigidity, and stability. Sheet metal coverings have a notch pattern to allow securing them on the side of mounting lates via M2.5 low profile mounting screws. Not all the open threaded bores has to be utilized, but just enough to secure the cover plates at critical points.

Above, utilizing the Littrow prism is not so trivial. In this case, the angle gets complex, if you have doubt about it, try constructing it in your lab. In optics, always have your feet on the ground, meaning to always use a line of reference. The nature of the cage system mechanics, with its 4 rod system, looks to be an impediment in optomechanical design because one would have a tough time with angles. Once that is resolved, the cage system becomes far more practical in doing prism work than table top experimentation. The reason is once you construct a self holding assembly like Optoform, you could easily rotate it but you can't do that with breadboards, and optical tables. In this case, all you have to do is build the binocular head assembly, and rotate it by 90 degrees.

Sheet Metal Covering

Cover sheets has been added to light seal, and dust seal the optics. The microscope is quite compact, and when the entire assembly is packed inside cover sheets, then the end user would think that it would also need to add rubber legs. When you deal with a complete instrument, then usability, and durability becomes a concern. Issues like strain belief for cabling, and usability to be easily operated by others come to play that would change the outlook of the microscope.

The Imaging System

An imaging microscope may be easily constructed with trinocular head, identical to the biological microscope we built earlier. In that arrangement, the CCD camera would be situated in front of the microscope. Optoform setups could be reconfigured to accommodate a variety of design options.

Fluorescent Microscopy

Basic concept of Fluorescence microscopy consisting of a UV light source, Excitation filter, Dichroic mirror, and a Barrier filter is implemented with Optoform, and in the next chapter, we'll explores scannig fluorescent microscopy.

Several filter/bemsplitter combinations must be offered to work with specific sample types. We'll be utilizing circular bandpass filtes for now but will eventually use standard Zeiss filters.

Designing the new mounts

A new mount will be needed to implement the beamsplitter slider so it will be built using Optoform's frame structure. We'll need to compete with existing microscopes on cost, and versatility. Once we implement it with Optoform, it will exceed in flexibility among other microscopes because it will provide a completely open architecture design.

Zeiss AxiosKop Fluorescent filter slider conists of Emission filter (5), Excitation filter (4), and Dichroic beamsplitter (2). The filter block is identical to slider in Axiovert

Designing the beamsplitter housing for Fluorescent filters

The idea would be to have a means to form a cube that is hollowed from inside out so it would allow mounts to slide in and out without obstruction. Let me show you what I mean: What we need to build is a beamsplitter housing that would

accept any number of filters on its four faces around a central beamsplitter (above). This is accomplished by side mounting the rods by a corner connector 40-144 that basically secures three rods side by side to provide clearance for sliding mounts 40-110 to be inserted without collision with the neighboring mounts. It would therefore allow inserting a multiplicity of beamspliiters, and filters without any obstruction. We could either side connect the sliding mount 40-110 to insert various filters or to switch between filters very rapidly, we could make an extended version. We'll also need to design a diagonal sliding mount to secure various beamsplitters, mounted in 30 mm lens cells. The 30 mm lens cell provides a 28 mm clearance aperture to provide the necessary beam path clearance when mounted at 45°.

Sliding Beamsplitter 40-148

I think we are there now to start constructing our beamsplitter assembly. Let's view the assembly constructed above. It takes 8 Rod Corner Connectors 40-144 to construct this cube.

Several sliding mounts 40-110 could be side connected to add as many filters one would wish to have, or a 3-position filter holder could be designed for securing a set of 3 filters for Emission, and another set to secure Excitation filters. If you notice there are four sides to the beamsplitter cube, securing the emission, transmission and the objective lens. What could we use the 4th aperture for?

The fourth side is utilized to secure a light trap. The light trap is the most crucial part of the beamsplitter assembly. It would influence the image contrast. Several designs are offered for light traps. One simple example would be a small can, painted dull black on the inside, filled with black anti static sponge.

Building our very own Fat Microscope

Lets now integrate our beamsplitter assembly with other sub assemblies we had constructed in past issues. The filter sliders are also shown. The light source could be Halogen but a high intensity Mercury or Xenon lamp is recommended. We'll be making one later. We now have to decide where we'll mount the beamsplitter assembly. The best option would be to mount it inside a larger housing to light seal the beam path. So we'll remove the upper, and lower 40-100 mounts,

Designing the Confocal Head for Optoform Microsocpe

In last section, we developed the central beamsplitter slider for Fluorescent microscope. Although Zeiss utilizes this scheme, their slider is a solid block which has to be pre-assembled before its insertion into the microscope. In our design, there are three sliders, that could be independently selected to get the desired emission/excitation/absorption effect. The standard filter size for Ziess is 25 mm, and the bemsplitter size is 25.5 x 36 mm. A high quality 3-filter/beamsplitter set will cost around \$1,200 each, adding up to \$3,600 just for filters.

Typical combinations that are available are: **546/ 580/ 590**, **485/ 510/ 515**, and **385/ 395/ 397** for Excitation/ Dichroic/ Emission filters respectively. As we see in LSM 510 (below), all the internal filters of Axiovert 2 microscope are bypassed, and the scan head has its own sets of filters, and beams-plitters. Looking back at our Optoform microscope, the placement of the Confocal head could be on the back side of 74-120 mount, behind the trinocular observation head we built in previous section.

Optoform Version of Confocal Scan Head

Lets now begin designing a Confocal Scan Head with Optoform. The basic design would be a combination of individually designed Optoform modules. But for now, let's see how a side view of the microscope would look like. At system level, if we were to copy Zeiss LSM 510 Confocal scanner, we'll have the simplified arrangement below: Light originates from a bright LED light source and collimation optics L1, goes through excitation filter set FW1, reflects off of beasplitter wheel BSW, reflects off of X-Y galvos, then through scan lens SL, and enters the light path of microscope through mirror M2, and M3, finally focused by an objective on the sample. The fluorescent light emitted from the sample goes through the objective lens, then reflects off of mirror M3, then M2, and goes through the galvos, passes through dichroic beamsplitter BSW, emission filter set FW2, and to the PMT detector. To start with, the filter wheels could be replaced with a particular filter set, and a dichroic beamsplitter. We don't know yet where to find the elliptical dichroic beamsplitters (Like those found in LSM 150). There is a better approach we could take to avoid Zeiss' spaghetti optical design, and this is how:

The Simplified Layout

Instead of filter wheels, why not utilize the same assembly we built for fluorescent microscopy? If we decided to motorize the system, we could devise linear actuators instead of a rotary filter wheel drive. So here is a basic design for the system. For PMT housing we could utilize the same module we developed for Strategene and was made available in classical Optoform catalog. It is made of black Derlyn, and has a rectangular lens mount on its front face for mounting cylindrical optics.

The detection side needs more work because the scan area is supposed to be a pinhole. So we'll need to have an X-Y stage like we saw in Zeiss LSM 510 to align the beam from the spot on the sample onto the PMT. In Zeiss design, there had to be compensation for a shift by the scan head laying on top of microscope. We'll also have the same challenge if this design is intended to be an add on module.

Integrating the Modules

So here it is, put together by connecting cubes A, B, C, and D (right), and after the installation of the necessary hardware: The galvo cubes, the beamsplitters, and filters, fold mirror, PMT tube, the pinhole, and the light source.

Let's now go back to the discussion we had about the chassis. We have the option of fitting this assembly inside a symmetrical housing (with the scan lens centered in the middle of the box, or

The accompanyig optics set 20-914 is designed to supply necessary optical elements to perform laboratory experiments. There is a condenser lens with matching reflector to collimate the Halogen lamp output. There is a single slit for spectroscopy (and perhaps Fourier Transform) experiments. There are the standard 10X objective, and eyepiece set. There is also a beamsplitter, and mirror set to build interferometers, and auto-collimators, and an equilateral prism for spectroscopy. The lamp socket 50-359 is connectrized with a connecting cable for standard 4 mm power supply sockets.

Optoform II Introductory Kit 40-706

The new Optoform Basic kit is designed to allow the end user to setup a multiplicity of optical experiments. The kit allows hands-on assembly of several optical instruments so its opto-mechanical capabilities could be studied. The rest is up to the user's own imagination, and cretivity to build their own projects. First lets examine what's in this introductory kit, and then we'll start constructing from basic experiments such as a telescope, and we'll do more complex setups such as an autocollimator, and a spectroscope.

This kit is a mixture of parts from the Micromax system, some of Microptiic 50 accessories, and the new Optoform 40 mounting plates. There are plenty of rods to do many complex setups. Micromax tubing is utilized mainly for focusing of optical elements or to extend the optical path.

40-706 Optoform Starter kit contains 60 parts. Various lab setups can be performed such as building simple telescopes, or an autocollimator, and other applications such as microscopy, spectrosopy, etc.

In the next pages, and the following issue, we will show how to set up these experiments, but the main goal is to prepare you to setup your own ideas, and be able to do problem solving in your own lab.

Placing support rods on the outside corners of Optoform mounts allows 25/30 mm mounted optics to be easily inserted, and taken out without obstruction. Up to 40 mm optics may now be fitted in between the rods.
